Researcher: Nansen**Date:** 12/5/22**Project Title:** Efficacy of Management Tools for Mealybug**Protocol #:** S22-005**PRnumbers:** 34406, 34407, 34408, 34409, 35069.34410, 29844**Narrative Summary (Results/Discussion)**

The citrus mealybug, *Planococcus citri*, is a common pest on citrus, as well as indoor ornamentals and landscape scrubs. Mealybugs are piercing-sucking insects that feed on plant phloem, which can reduce plant growth. Also, the insects excrete sticky honeydew, which can cause growth of black sooty mold. Indoor-grown plants are especially vulnerable to mealybug infestations, because of the mild temperatures and the absence of most natural enemies. Mealybugs are generally challenging to manage with insecticides (<http://ipm.ucanr.edu/PMG/PESTNOTES/pn74174.html>).

The purpose of this study was to determine efficacy of new active ingredient formulations and new biopesticides for managing mealybug infestations environmental horticulture plants. A total of 77 individually potted Common Coleus (*Plectranthus scutellarioides*) plants were used and subjected to one of 11 treatments (seven replications). Four of the treatments were one dosage of insecticides applied via foliar, six of the treatments were one product of insecticides at multiple dosages applied via foliar, and one treatment was water only (positive control). After initial experimental infestations, numbers of egg masses, crawlers, and mobiles (immatures larger than crawlers + adults) were assessed: -1 (baseline), 3, 7, 14, and 28 days after onset of spray applications (= days after application, DAT). Individual plants were also assessed for possible signs of phytotoxicity of both leaves and flowers.

We predicted that foliar applications of insecticides would cause significant decrease in Mealybug counts over time compared to counts on positive control plants. We also predicted that foliar applications of insecticides would not cause significant increase in phytotoxicity of neither leaves nor flowers.

In several previous reports, we have highlighted the issue that Capsil as an adjuvant is: 1) not part of all treatments, and 2) it is not included as a second control (Capsil only). For the experimental to meet basic standards, it is important Capsil by itself is included as a treatment. This is of particular importance as some of the insecticides, which in this and previous studies have yielded promising results, include Capsil in formulations. As observed in previous studies, consistent and significant reductions in average counts of mealybug egg masses, crawlers, and mobiles (compared to water treated control plants) were observed at 28 DAT with several of the insecticide treatment. In this year's study, highest and most consistent reductions (compared to water treated controls) were obtained with the following treatments: ISM 555 applied at both low and high doses (with adjuvant Capsil), SP3014 (with adjuvant Capsil), Distance (without Capsil), TetraCURB Max (without Capsil), and V-10433 (without Capsil). Neither average width nor average height of Common Coleus plants was significantly affected by insecticide treatments. None of the treatments were found to cause any detectable foliar phytotoxicity and/or signs of phytotoxicity of flowers. Based on a data from previous IR4 project, we have published an article about use of optical sensing to detect and quantify phytotoxicity in ornamental plants (<https://doi.org/10.21273/HORTTECH04866-21>).

Results Table

PI Christian Nansen is licensed to apply pesticides and performed all preparations of pesticide formulations and spray applications. A video about our approach to pesticide applications and its role in research and teaching is available: <https://www.youtube.com/watch?v=DtYFrvkguKQ>.

Mealybug – egg masses

Table 1 shows that there were no significant differences among treatments at the onset of the study (-1 and 3 DAT). At 7 DAT, plants sprayed with ISM-555 at the high dose had significantly less egg masses than the average of control plants. At 10 DAT, all treatments had significantly less egg masses than the average of control plants, and this significant difference persisted until 28 DAT (except for plants treated with MBI 306). Overall, all treatments caused significant reduction in mealybug egg masses 10-28 DAT.

Mealybug – crawlers

Table 2 shows that there were no significant differences among treatments at the onset of the study (-1 DAT). At 3 DAT, plants sprayed with TetraCURB Max or V-10433 had significantly less mealybug crawlers than the average of control plants. This significant reduction persisted over time until 28 DAT. At 10 DAT, all treatments showed significant reduction in average crawler counts, except for MBI 306 applied at the high dose. At 28 DAT, all treatments showed significant reduction in average crawler counts. Overall, Distance and both dosages of ISM-555 showed the most consistent reduction in average crawler counts.

Mealybug – mobiles

Table 3 shows that there were no significant differences among treatments at the onset of the study (-1 and 3 DAT). At 7 DAT, TetraCURB Max and Distance treatments caused a significant reduction in average counts of mobiles, and these effects persisted throughout the study period. At 10 DAT, all treatments caused a significant reduction in average counts of mobiles compared control plants (except for plants treated with MBI 306). At 28 DAT, all treatments showed significant reduction in average mobile counts. Overall, TetraCURB Max, Distance and both dosages of ISM-555 showed the most consistent reduction in average mobile counts.

Plant morphometric

Figure 1 shows average plant morphometrics. Neither average plant height (Figure 1a) nor average plant width (Figure 1b) varied significantly among treatments at the two time points [-1 (orange) and 28 (turquois) DAT].

Phytotoxicity

None of the 10 treatments were found to cause any detectable foliar phytotoxicity and/or signs of phytotoxicity of flowers. Based on a data from previous IR4 project, we have published an article about use of optical sensing to detect and quantify phytotoxicity in ornamental plants (<https://doi.org/10.21273/HORTTECH04866-21>).

This study was conducted in a research greenhouse on the University of California campus in Davis, CA. Plants (Common Coleus) were obtained from Greenheart Farms (Arroyo Grande, CA) and transplanted into UC Agronomy mix (equal parts peat, sand, redwood bark and scoria) in 6.5-inch pots. Plants received daily irrigation and fertilizer via a drip system. Plants were infested twice on 5/17/22 and 5/24/22 to ensure consistent Mealybug infestation levels in all plants. Beneficials (*Amblyseius Cucumeris* and *Phytoseiulus Persimilis*) were applied on 4/21/22. We used cottony egg masses from citrus mealybugs (*Planococcus citri*) from a colony maintained by the Nansen lab. To assess mealybug establishment on the plants immediately before onset of foliar applications (DAT = 0), a precount was done on DAT-1, 6/13/22. There were 11 treatments, each replicated seven times (coleus plants = 77). Pump spray applications were conducted using a Dramm BP-4 backpack sprayer.

For mealybug counts, one fully matured compound leaf per plant, consisting of 5 leaflets, was selected per plant, from an infested area. Egg masses, crawlers, mobiles (immatures larger than crawlers + adults) were counted on both sides of the compound leaf. Leaves of approximately the same size were selected assessment. Regarding morphometrics, plant height and width were measured. Phytotoxicity of leaves was scored on a 0 to 10 scale (0 = no phytotoxicity, 10 = dead plant). Phytotoxicity of flowers was also scored on a 0 to 10 scale, with 0% = no flowers showing signs of phytotoxicity and 100% = to all flowers showing signs of phytotoxicity. Thus, flower phytotoxicity was based on dichotomous assessment of individual flowers (phytotoxicity yes/no). Before transplanting, predatory mites (*Phytoseiulus persimilis*) were released in the greenhouse to control spider mite infestations.

Statistical analysis: Separate pairwise tukey analyses of variance were performed in R [library(multcomp)] for each combination of days after onset of treatments.

Raw Data: Dates, treatments, counts egg-mass, mobiles, and crawlers, and environmental conditions.
Please see attached file.

Application Equipment: Dramm hydraulic sprayer

Christian Nansen performed all pesticide spray applications.

TAB NAME: Assignment

Input damage assessment. Input treatment numbers starting from treatment 1 to the final treatment number and repeat until all plants are assigned
For example, if there are 3 treatments, then cell C5 = 1, C6 = 2, C7 = 3, C8 = 1, C9 = 2 etc.

Copy columns H-J to M-O. Then sort each of the damage assessments by column L for columns L-O. For example, if column M rows 6-30 are "1", sort columns L-O rows 6-30 based off column L. Repeat for the appropriate rows for assessments "2" and "3".
